

Installing Ember was a pain in the ass, you install everything through the command line, although there are packages you can install into sublime or atom but the base is through terminal. I think I installed it at least four times before it finally stayed in my system. I even went through and uninstalled homebrew, node.js, npm, watchman, phantomjs, and bower and then reinstalled them all. There went another hour.

to install run: **npm install ember-cli -g**

to verify it installed run: **ember -v**

to create a new app run: **ember new [name of app i.e. my new app]**—this will create ALL folders and starter files.

then cd into your new app folder because you can't run any ember commands unless you are in that folder in terminal.

To see what you're working on in Ember, you have to use the command line  
run: **ember server**

That connects you to the server and you can type into your browser <http://localhost:4200> your site will show up there. If you just drag your index to the browser you will see nothing and get frustrated.
